

# Khovanov homology over $\mathbb{C}[\alpha]$

- Recall in Bar-Natan's cobordism model of Khovanov homology, we imposed relations:

$$\text{cap} = 0 \quad \text{cup} = 2$$

$$\text{cylinder} = \frac{1}{2} \text{cup} \text{cap} + \frac{1}{2} \text{cap} \text{cup}$$

and  $\text{triple} = 0$

- The last one is actually unnecessary:  
it's just there to make Hom spaces finite dimensional over  $\mathbb{C}$ .

But it's a bad tradeoff — instead, we should write  $\alpha = \text{triple}$  and absorb it into the coefficient ring.

- First a little calculation from yesterday:

$$\begin{aligned}
 \text{[Diagram: two circles joined at a neck]} &\stackrel{\text{neck cutting}}{=} \frac{1}{2} \text{[Diagram: two circles side-by-side]} + \frac{1}{2} \text{[Diagram: two circles side-by-side]} \\
 &= 2 \text{[Diagram: two circles side-by-side]}
 \end{aligned}$$

So  $\text{[Diagram: two circles joined at a neck]} = 0$ .

- Then

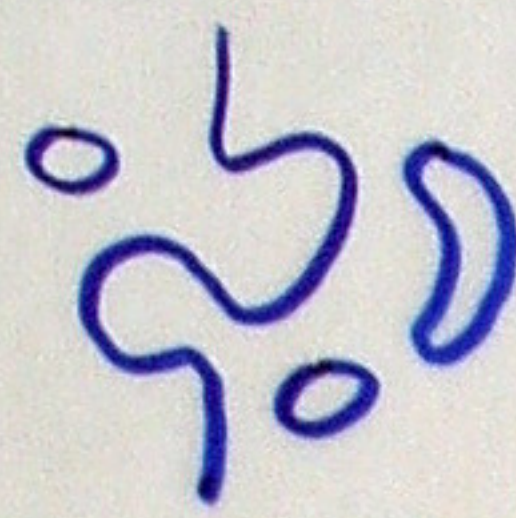

$$\begin{aligned}
 \text{[Diagram: rectangle with two handles]} &\stackrel{\text{neck cutting}}{=} \frac{1}{2} \text{[Diagram: rectangle with one handle]} + \frac{1}{2} \text{[Diagram: rectangle with two handles]} \\
 &= \frac{\alpha}{2} \text{[Diagram: rectangle]}
 \end{aligned}$$

- We can run this both ways, eliminating even numbers of handles for  $\alpha$ , or 'reattaching'  $\alpha$  to a sheet. Thus we have two descriptions of  $\text{Hom}(\cdot, \cdot)$ :

$$\text{Hom}(\cdot, \cdot) = \langle \text{[Diagram: circle with a neck]} \rangle = \langle [\alpha] \{ \text{[Diagram: rectangle]}, \text{[Diagram: rectangle with one handle]} \} \rangle$$

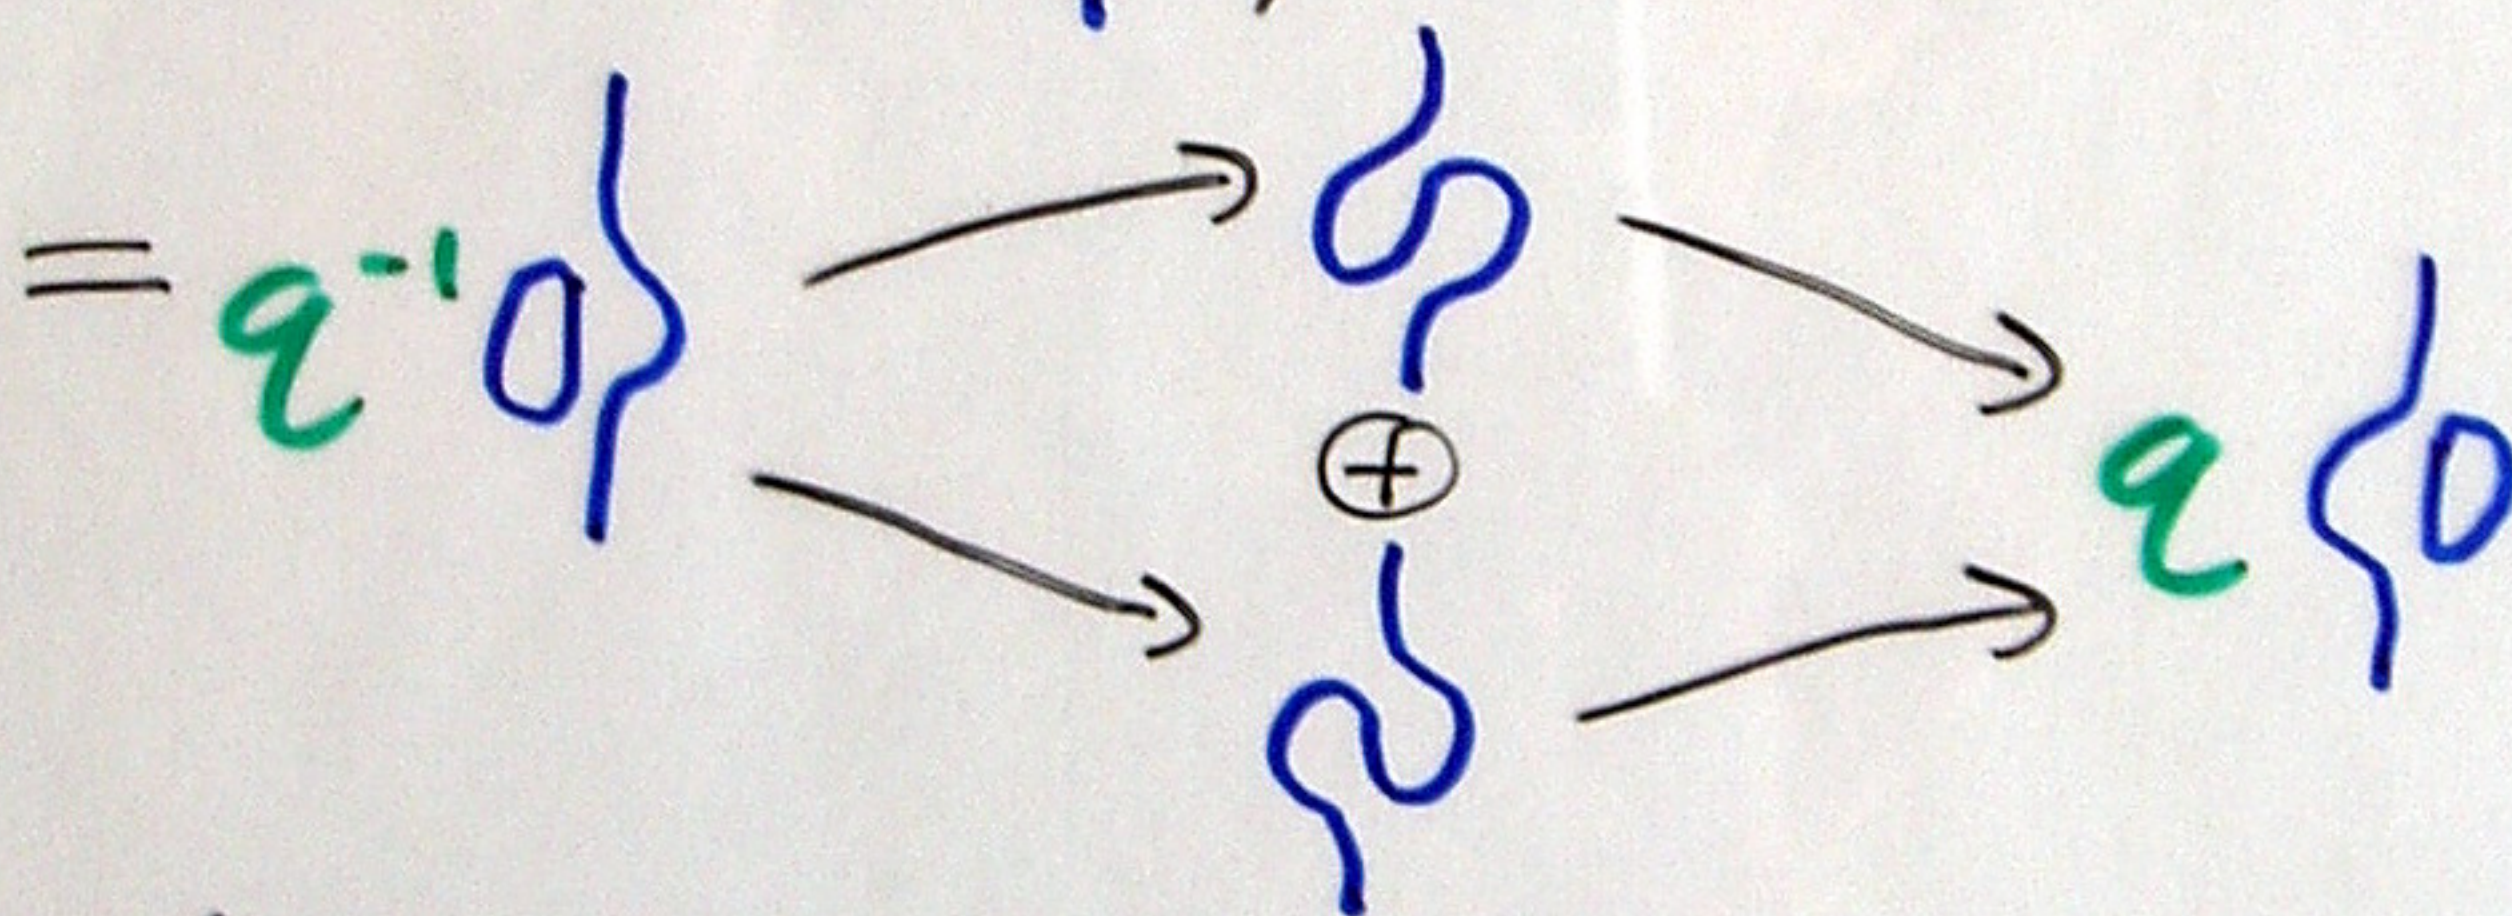

# Cutting open the knot

- Before calculating Khovanov homology, cut open the link at a chosen point, producing a "1-1 tangle".
- Each resolution of a 1-1 tangle looks like

; a single "through strand" with circles on either side.

- We can take the complex for a 1-1 tangle, e.g.

$$Kh_{cut}(\text{link}) = Kh\left(\begin{array}{c} | \\ \text{---} \\ | \end{array}\right)$$

and "de-loop" it, so every object is a direct sum of strands:

$$\cong \begin{array}{c} q^{-2} \\ \oplus \\ \end{array} \xrightarrow{(\begin{smallmatrix} \vdots \\ \vdots \\ \vdots \end{smallmatrix})} \begin{array}{c} \oplus \\ \end{array} \xrightarrow{(\begin{smallmatrix} \vdots \\ \vdots \\ \vdots \end{smallmatrix})} \begin{array}{c} \oplus \\ q^2 \end{array}$$

# Gaussian elimination over $\mathbb{C}[t]$

- We saw yesterday how to simplify the complex for a tangle by "Gaussian elimination", successively stripping off invertible matrix entries, turning them into contractible direct summands.
- Today, this won't get us as far:  $\begin{bmatrix} \rightarrow \\ \rightarrow \end{bmatrix}$  is not invertible. Nevertheless, we can strip off the lowest power of  $\begin{bmatrix} \rightarrow \\ \rightarrow \end{bmatrix}$ .

If  $k \leq l, m \in \mathbb{N}$ , and  $\varphi$  is an isomorphism, there's an isomorphism of complexes:

$$\begin{array}{ccccccc}
 A & \xrightarrow{\begin{pmatrix} \beta \\ \gamma \end{pmatrix}} & \begin{array}{c} B \\ \oplus \\ C \end{array} & \xrightarrow{\begin{pmatrix} t^k \varphi & t^l \lambda \\ t^m \mu & \nu \end{pmatrix}} & \begin{array}{c} D \\ \oplus \\ E \end{array} & \xrightarrow{\begin{pmatrix} \delta & \epsilon \end{pmatrix}} & F \\
 \downarrow & & \downarrow & \cong & \downarrow & & \downarrow \\
 A & \xrightarrow{\begin{pmatrix} 0 \\ \gamma \end{pmatrix}} & \begin{array}{c} B \\ \oplus \\ C \end{array} & \xrightarrow{\begin{pmatrix} t^k \varphi & 0 \\ 0 & \nu - t^{l+m-k} \mu \varphi^{-1} \lambda \end{pmatrix}} & \begin{array}{c} D \\ \oplus \\ E \end{array} & \xrightarrow{\begin{pmatrix} 0 & \epsilon \end{pmatrix}} & F
 \end{array}$$

- Since our matrix entries are homogeneous elements of  $\mathbb{C}[\begin{bmatrix} \rightarrow \\ \rightarrow \end{bmatrix}]$ , they're all either 0 or  $\begin{bmatrix} \rightarrow \\ \rightarrow \end{bmatrix}^k \varphi$  for some  $k \in \mathbb{N}$ ,  $\varphi \in \mathbb{C}^x$ .

- The Gaussian elimination lemma decomposes our complex into direct sums of the following short complexes:

$$E = )$$

$$C_n = q^{-2n} ) \xrightarrow{\begin{matrix} \square \\ \circ \\ \square \end{matrix}^n}$$

each with grading a homological height shifts attached. Thus at the level of complexes,

$$Kh_{\text{cut}}^{\text{cut}}(L) \cong \sum_{x,r} a_{x,r} q^x t^r E + \sum_{x,r,n \geq 1} b_{x,r,n} q^x t^r C_n$$

- Taking homology (implicitly replacing  $)$  with  $\text{Hom}(\quad, \quad) = \mathbb{C}[t]$ )

$$H^{\bullet}(\quad) = \mathbb{C}[t] \quad (\text{in height } \bullet = 0)$$

$$H^{\bullet}(q^{-2n} \xrightarrow{\begin{matrix} \square \\ \circ \\ \square \end{matrix}^n}) = \mathbb{C}[t] / t^n = 0$$

There's one generator in homology for each indecomposable complex, and it's either "free" or "t-torsion".

The fancy version of all this would say

- " $\mathbb{C}[t]$  has homological dimension 1"
- "Kom( $\mathbb{C}[t]$ -modules) is Krull-Schmidt,"  
i.e. has unique decomposition into indecomposables

Observe  $E$  and  $C_n$  are not simple.

(exercise, write down all the chain maps between them.  
which ones are homotopically trivial?)

Be careful with "torsion" here: everything is over  $\mathbb{C}$ , so this is orthogonal to the also-interesting notion of  $\mathbb{Z}$ -torsion in Khovanov homology.  
Nothing  $\text{Pim}$  saying today really works over  $\mathbb{Z}$ .

# Recovering the usual invariant:

- We need to close the cut open invariant, and set  $\alpha = 0$ .

$$E = \left( \begin{array}{c} \text{close} \end{array} \right) \circlearrowleft \xrightarrow{\text{delooping}} \mathbb{Z}\phi \oplus \mathbb{Z}\phi^{-1}$$

$$\xrightarrow{\text{take Hom}} \mathbb{Z}\mathbb{C} \oplus \mathbb{Z}\mathbb{C}$$

$$C_1 = \mathbb{Z}\phi^{-2} \xrightarrow{\text{close}} \mathbb{Z}\phi^{-2} \circlearrowleft \xrightarrow{\text{delooping}} \mathbb{Z}\phi^{-2}$$

$$\begin{array}{ccc} \mathbb{Z}\phi^{-3} & \begin{pmatrix} 0 & 1 \\ \alpha & 0 \end{pmatrix} & \mathbb{Z}\phi^{-1} \\ \oplus & & \oplus \\ \mathbb{Z}\phi^{-1} & & \mathbb{Z}\phi \end{array}$$

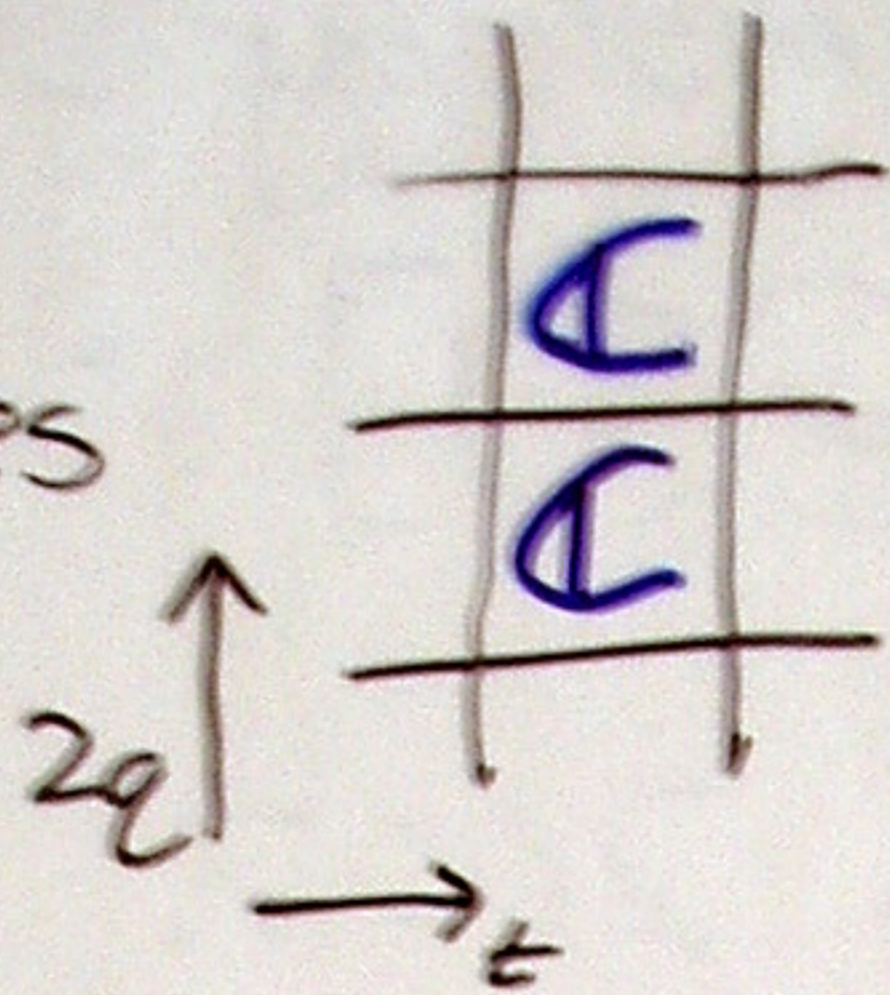

$$\xrightarrow{\text{htpy}} \mathbb{Z}\phi^{-3} \xrightarrow{\alpha=0} \mathbb{Z}\phi$$

$$\xrightarrow{\text{take Hom}} \mathbb{Z}\mathbb{C} \oplus \mathbb{Z}\mathbb{C}$$

(without setting  $\alpha = 0$ , we would have just got  $\mathbb{Z}\mathbb{C}[\alpha]/\alpha = 0$ .)

• Thus in classical Khovanov homology

$E$  contributes

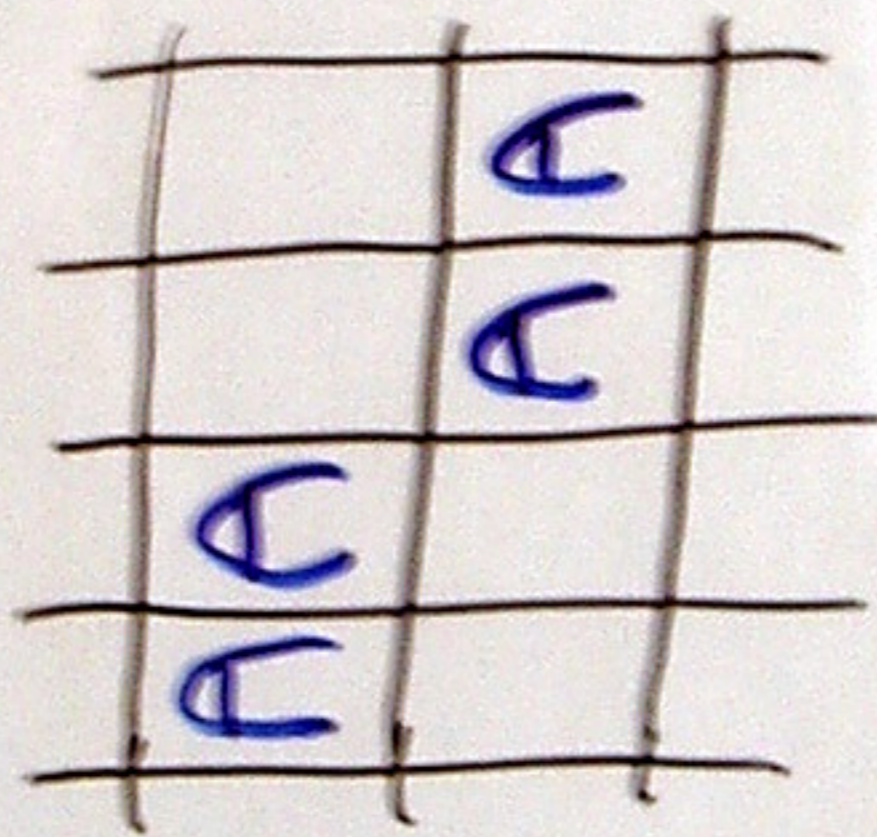

often called an "exceptional pair"

$C_1$  contributes

called a "knight's move"

$C_2$  contributes

indistinguishable from a pair of knight's moves.

$C_3$  contributes

, and so on.

(However, as far as I know  $C_{3,3}$  hasn't yet been seen in the wild.)

# Some "phenomenology"

- In the homology of a knot, there's a single copy of  $E$ , in homological height 0. Its  $q$ -grading is the "Rasmussen  $s$ -invariant".
- In alternating knots, only  $C_1$  shows up, and they're all "on diagonal":

$$\text{Kh}_{\text{alt}}(K^{\text{alternating}}) = q^s E + \sum_r b_r q^{s+2r} t^{-r} C_1$$

- $C_2$  first appears in  $\mathcal{S}_{1,9}$ , and is eventually common in non-alternating knots, especially closures of positive braids and torus knots.
- I haven't seen a  $C_3$  yet, but there's no reason not to expect them?

# Lee homology

- We can recover Lee homology by setting

$$\text{[Diagram: a red box containing three circles]} = \mathbb{Z} \in \mathbb{C}^\times.$$

First, notice

- $\text{[Diagram: a red box with a circle inside]} \circledast$  is now invertible:  $\text{[Diagram: a red box with a circle inside]} \circledast \frac{2}{\mathbb{Z}} \text{[Diagram: a red box with a circle inside]} = \frac{2}{\mathbb{Z}} \frac{\alpha}{2} \text{[Diagram: an empty red box]} = \text{[Diagram: an empty red box]}$
- $\text{[Diagram: an empty red box]}$  splits into orthogonal idempotents:

$$\text{[Diagram: a green box]} = \frac{1}{2} \text{[Diagram: an empty red box]} + \frac{1}{\sqrt{2}\mathbb{Z}} \text{[Diagram: a red box with a circle inside]}$$

$$\text{[Diagram: a purple box]} = \frac{1}{2} \text{[Diagram: an empty red box]} - \frac{1}{\sqrt{2}\mathbb{Z}} \text{[Diagram: a red box with a circle inside]}$$

- What happens?

**E** survives

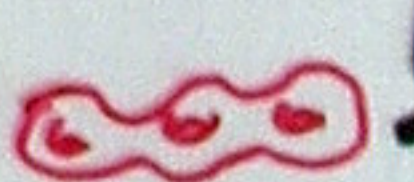

each  $C_n$  becomes contractible.

- People used to say "Lee homology is boring,"  
( $2^{\#\text{components}} - 1$  copies of **E**)

"but boring in an interesting way."

There's a spectral sequence

$$E_1 = CKh, \quad E_2 = Kh, \quad \dots \quad E_\infty = Kh_{Lee}$$

- This is easy to understand using  $Kh$  !

- After delooping the complex for a 1-1 tangle, each matrix entry appearing in a differential is an element of

$$\text{Hom}(, ) = \mathbb{C}[\alpha] \left\{ \square, \begin{array}{c} \square \\ \cup \end{array} \right\}$$

We can write the differential as

$$d = d_0 + \alpha d_4 + \alpha^2 d_8 + \dots$$

- Associated to this is a spectral sequence

$$(CKh, d_0) \rightsquigarrow (H^*(C, d_0), d_4^*) \rightsquigarrow (H^*(H^*(C, d_0), d_4^*), d_8^*) \rightsquigarrow \dots$$

The second page is normal Khovanov homology;

$$\text{at } \alpha = 0, d_0 = d.$$

The  $\infty$ -page is  $H^*(CKh, d_0 + d_4 + d_8 + \dots)$ ,

which is Lee homology; at  $\alpha = 1, d = d_0 + d_4 + d_8 + \dots$

Don't be scared, each step of this spectral sequence really is a complex!

First, write

$$d^2 = d_0^2 + \alpha(d_4 d_0 + d_0 d_4) + \alpha^2(d_8 d_0 + d_4 d_4 + d_0 d_8) + \dots = 0.$$

Next, observe  $d_4: \ker d_0 \hookrightarrow$

$$d_0 x = 0 \implies d_0 d_4 x = -d_4 d_0 x = 0.$$

On  $\ker d_0 / \text{im } d_0$ ,  $d_4^2 = 0$ :

$$d_4^2 x = -d_8 d_0 x - d_0 d_8 x = -d_0 d_8 x \in \text{im } d_0.$$

and so on for higher levels....

# Genus bounds from the $s$ -invariant.

- Write  $E(L)$  for the "E part" of  $\text{Kh}_{\text{red}}(L)$
- A cobordism  $\Sigma: L_1 \rightarrow L_2$  gives a map of grading  $\chi(\Sigma); \text{Kh}(\Sigma): \text{Kh}(L_1) \rightarrow \text{Kh}(L_2)$

If  $\Sigma$  is connected, this map is nonzero when restricted to  $E(L_1) \rightarrow E(L_2)$  (there's some work to do there!)

- For  $L_1 = \emptyset$  and  $L_2 = K$ , a knot,

$$\text{Kh}(\Sigma): E \xrightarrow{\text{[diagram of } K \text{ with } k \text{ crossings]}} q^{s(K)} E$$

Calculating gradings,  $\chi(\Sigma) = s(K) - 2k$ ,  
so  $\chi(\Sigma) \leq s(K)$

The same argument with the mirror image says  $\chi(\Sigma) \leq -s(K)$ , so

$$\chi(\Sigma) \leq -|s(K)|.$$

- For a cobordism  $\Sigma': \emptyset \rightarrow K$  we have  $\chi(\Sigma') \leq -|s(K)| + 1$

# Genus bounds for links, too!

- First switch to the 'framing grading'  $t \rightsquigarrow z^2 q^{-3}$
- To obtain a genus bound for surfaces inducing an orientation differing in writhe from the original by  $\Delta$ , look at all copies of  $E$  in height  $z^{-\Delta}$ :

$$\chi(\Sigma) \leq - \frac{\min(r)}{z^{-\Delta} q^r E} + 1$$

and

$$\chi(\Sigma) \leq \frac{\max(r)}{z^{-\Delta} q^r E} + 1$$

- Unfortunately, this can be very weak. For example, if  $\{r\} = \{-1, 1\}$  we only learn  $\chi(\Sigma) \leq 2$ .

# An Example.

$$Kh \cong \left( \begin{array}{c} \text{[Diagram of a genus-3 surface with orientation arrows]} \\ L^4 \text{al} \end{array} \right) = q^3 E + z^6 C_1 + q^{-1} z^8 E$$

- Thus  $\chi \leq -3 + 1 = -2$  for surfaces inducing the given orientation, which is sharp:

- The other orientation differs in writhe by  $-8$ , so we look at the  $q^{-1} z^8 E$  term, obtaining  $\chi \leq 0$ , also sharp:
