## LYMPH-TOFU, Kauffman, and ...?

$\downarrow$

HOMFLY-PT-U

- Why do the HOMFLY and Kauffman polynomials exist?  
 They are both two variable polynomial invariants of links.  
 They are explained by families of Lie-algebras, which  
 can be coherently quantised.

$$\text{Homfly}(G)(a, z) = \bigcup_{G \in \text{Rep } U_q(\mathfrak{gl}_n)}$$

when  $a = q^n$ ,  $z = q - q^{-1}$ .

It seems there may be another such polynomial.

Families of 'Lie algebras':

classical	classical	classical	exceptional
classical			
$gl_t, \mathfrak{o}_t$			Deligne's exceptional series.
quantum		quantum	
classical		exceptional	
Homfly, Dubrovnik			

(2)

- The Lie algebras  $gl(n, \mathbb{C})$  show a variety of uniform behaviour
  - the f.d. irreps are indexed by partitions,  $n$  only enters through a restriction that there are at most  $n$  rows.
  - for a fixed partition, the dimension of the irrep is a rational function of  $n$
  - the Littlewood-Richardson rule describes  $\otimes$ -products

$$\begin{array}{c} \square \\ \square \end{array} \otimes \begin{array}{cc} \square & \square \\ \square & \square \end{array} = \begin{array}{cc} \square & \square \\ \square & \square \end{array} \oplus \begin{array}{c} \square \\ \square \end{array}$$

vanishes when  $n=2$

These are explained by Deligne's  $gl_t$ , which is essentially a skew theory

based on (unembedded) oriented curves, modulo a relation:

$$gl_t = \mathbb{Q}[d] \left\{ \begin{array}{c} \nearrow \searrow \\ \diagdown \end{array} \right\} / \alpha = d$$

We can think of this as a (pivotal) category ③

$$\text{Obj}(gl_t) = \{\text{words in } \mathbb{E}^{\uparrow, \downarrow}\}$$

~~$$gl_t(\uparrow\downarrow\uparrow\downarrow \rightarrow \uparrow\downarrow\uparrow) = \mathbb{Q}[d] \{ \text{tangles} \} / Q=d$$~~

In any pivotal category, we have the negligible ideal

$$N = \left\{ \begin{array}{c|c} \text{diagram} & \vee \text{ diagram}, \quad \text{diagram} \\ \hline x & y \\ \hline \end{array} \right\} = \text{zero}.$$

### Theorem

- Generically  $N(gl_t) = \{0\}$
- Generically, the idempotent completion is semisimple, with simples labelled by partitions, satisfying the LR rule.
- At  $t=n \geq 0$

$$gl_t/N \cong \text{Rep gl}(n, \mathbb{C})$$

$\uparrow \longmapsto \mathbb{C}^n$ .

This explains all the uniform behaviour!

Similarly there is an unoriented skein theory  $O_t$  explaining the uniform behaviour of  $O(n)$  and  $Sp(2n)$ .

(4)

Each of the Lie algebras  $\mathfrak{gl}(n, \mathbb{C})$  has a quantisation  $U_q \mathfrak{gl}(n, \mathbb{C})$ ,

and  $\text{Rep } U_q \mathfrak{gl}(n)$  is a braided  $\otimes$ -category.

We get link invariants

$$\text{Diagram} \in \text{Rep } U_q \mathfrak{gl}(n)$$

is a rational function in  $q$ , depending on  $n$ .

These link invariants all fit together into a 2-variable polynomial

$$\text{Homfly}(\text{Diagram})(a, z) = \text{Diagram} \in \text{Rep } U_q \mathfrak{gl}(n)$$

at  $a=q^i, z=q^{-i}$ .

This is explained by the existence of a braided  $\otimes$ -category over  $\mathbb{Q}[a, z]$ :

$$\text{HOMFLY} = \left\{ \text{oriented tangles} \right\} / \begin{array}{l} \text{Diagram} - \text{Diagram}' = z \\ \text{Diagram} = a \end{array}$$

$$(\text{as a consequence}, d = C = \frac{a-a^{-1}}{z})$$

$$\begin{aligned} &= \frac{q^n - q^{-n}}{q - q^{-1}} = q^{n-1} + q^{n-3} + \dots + q^{-n+1} \\ &= n \quad \text{at } q=1 \end{aligned}$$

Theorem • HOMFLY is generically semisimple (after idempotent (5) completion)  
 (with simples labelled by partitions)

- At  $a=q^n$ ,  $z=q-q^{-1}$ ,

$$\text{HOMFLY}/_N \cong \text{Rep } U_q \text{ gl}(n)$$

$\uparrow \longmapsto \mathbb{C}(q)^n$

Similarly, the Dubrovnik skein relation explains the uniform behaviour of  $\text{Rep } U_q \text{ oh}$  and  $\text{Rep } U_q \text{ sp}(n)$ .  
 ~Kauffman

$$\begin{array}{c} X - X = z ( ) (- \curvearrowleft) \\ | P = a \end{array}$$

$$(\text{and so } O = \frac{a-a^{-1}}{z} + 1.)$$

At  $a=q^{4n}$ ,  $z=q^2-q^{-2}$ , Dubrovnik/ $_N \cong \text{Rep}^{\text{vector}} U_q \text{ so}(2n+1)$

$$a = q^{2n+1}, z = q - q^{-1},$$

$$\cong \text{Rep}^{\text{vector}} U_q \text{ so}(2n)$$

$$a = -q^{2n+1}, z = q - q^{-1},$$

$$\cong \text{Rep } U_q \text{ sp}(2n)^{\text{unimod.}}$$

(6)

Vogel, Cvitanovic, Cohen-de Mann, and Deligne  
 have noticed certain uniform behaviour amongst  
 the exceptional Lie algebras  $g_2, f_4, e_6, e_7, e_8$ .

The simplest phenomenon is seen in  $\dim \text{Inv}(g^{\otimes k})$ :

$g$	$k=0$	$k=1$	$k=2$	$k=3$	$k=4$	$k=5$	$k=6$	$k=7$
$g_2$	1	0	1	1	5	16	80	436
$f_4$	1	0	1	1	5	16	80	436
$e_6$	1	0	1	1	5	17	90	542
$e_7$	1	0	1	1	5	16	80	436
$e_8$	1	0	1	1	5	16	79	421

Deligne proposed an explanation in terms of a  
 skein theory based on (vertex-oriented) ~~planar~~ (unbedded)  
 cubic graphs, over  ~~$\mathbb{Q}$~~   $\mathbb{Q}(d)$

Except  ~~$\text{graph}$~~  =  $\left\{ \begin{array}{c} \text{graph} \\ \text{graph} \end{array} \right\}$  /

- $O = d$
- $O = \text{zero}$
- $O = 6/$
- $\Delta = 3\lambda$

$$\cancel{\text{graph}} - \cancel{\text{graph}} + \cancel{\text{graph}} = \text{zero} \quad (\text{IHx})$$

$$\text{graph} = \cancel{\text{graph}} + \cancel{\text{graph}} + \frac{30}{d+2} (\cancel{\text{graph}})(+\text{graph}) \quad (\text{the exceptional relation})$$

(7)

We then have:

Conjecture (Deligne, more or less)

- ~~Except~~ Except is generically semisimple.

- Except( $O \rightarrow O$ ) =  $\mathbb{Q}(d) \cdot \phi$ .  
the "space of closed diagrams"

- At  $d = \dim g$ , for  $g = g_2, f_4, e_6, e_7, e_8$ ,

$$\text{Except}/N \cong \text{Rep } g \quad (\text{or } \text{Rep } e_6^{2/2} \text{ when } g = e_6)$$

$$I \longrightarrow g$$

$$J \longrightarrow [J: g \otimes g \rightarrow g]$$

(It is at least easy to see that there is a functor

$$\text{Except}/N \rightarrow \text{Rep } g.)$$

(and not too hard to see it is an isomorphism)

This would depend on two subconjectures:

Conjecture 1: the relations suffice to evaluate any closed cubic graph

(e.g. one can show that any  $(2n+1)$ -gon can be rewritten in terms of 'simpler' diagrams)

(In fact, a wild conjecture is that this is even possible without the exceptional relation!)

Conjecture 2: this evaluation is consistent (i.e. gives a unique answer)

(8)

Both seem hard to prove!

But conjecture 2 may be easy to disprove —

it would suffice to exhibit some

cubic graph, and two different ways to evaluate it.

This would give a polynomial in  $d$ , which must vanish.

Certainly  $d=14, 52, \dots$  must be roots.

(Notice we couldn't have done this to break  $g_{1,1}$ ; infinitely many points actually exist.)

Enough points on the exceptional curve actually exist to ensure ~~such a~~ ~~cubic graph must be~~ ~~rela~~  
that a minimal example must be quite large....

### Examples

$$\begin{aligned} \text{1) } & \text{Diagram} = \text{Diagram} + \text{Diagram} + \frac{30}{d+2} (\text{Diagram} + \text{Diagram} + \text{Diagram}) \\ & = 2 \cdot 3 \cdot 3 \cdot 6 \cdot d + \frac{30}{d+2} (2 \cdot 6 \cdot 6 \cdot d + 3 \cdot 6 \cdot d) \\ & = 108d + \frac{2700d}{d+2} \end{aligned}$$

The Jacobi relation lets us simplify any  $(2n+1)$ -gon:

$$\text{Diagram} - \text{Diagram} = -\text{Diagram} = \text{Diagram} + \text{Diagram} + \text{Diagram} + \text{Diagram} - \text{Diagram}$$

$$\text{Diagram} = \frac{1}{2} [\text{Diagram} + \text{Diagram} + \text{Diagram} + \text{Diagram}]$$

## Evidence (Cohen de-Mann)

(8½)

One can compute how  $g^{\otimes k}$  decomposes into minimal idempotents for  $k \leq 3$ .

This agrees with the decomposition for the exceptional Lie algebras, and gives the dimensions of the irreps as rational functions in  $d$ .

Dissatisfied by the number of things we don't know

(9)

how to prove, we decided to make some more conjectures:

~~Conjecture~~

Let  $Q_{\text{Except}} = Q(v, w) \{ \text{cubic tangles} \}$

$$O = d(v, w) \quad \mathcal{D} = v^{12} \curvearrowleft$$

$$Q = \text{zero} \quad \mathcal{Q} = -v^6 \curvearrowleft$$

$$v^{-3} \begin{array}{c} \diagup \\ \diagdown \end{array} -v^{-1} \begin{array}{c} \diagup \\ \diagdown \end{array} +v \begin{array}{c} \diagup \\ \diagdown \end{array} + d(v, w) \left( \begin{array}{c} \diagup \\ \diagdown \end{array} + v^{-4} \right) \left( +v^4 \right) = \text{Zero.}$$

$$d = -\frac{(w-w^{-1})(wv-w^{-1}v)}{v-v^{-1}}$$

Theorem<sup>(MST)</sup> A skein theory for knotted trivalent graphs with  $\dim P_k \leq 1, 0, 1, 1, 5$

is either small and well-understood.

one other 1-parameter family,

or  $Q_{\text{Except}}$ .

$$d = -\frac{(v^2+v^{-2})x}{wv^5-w^{-1}v^5} \times \frac{wv^5-w^{-1}v^5}{w-w^{-1}} \times \frac{wv^6-w^{-1}v^6}{wv^4-w^{-1}v^4}.$$

Theorem<sup>(MST)</sup> With  $d = q \dim(g)$ ,  $v = q^{<\lambda_{\text{ad}}, \lambda_{\text{ad}} + \rho>}$

$$Q_{\text{Except}} / N \xrightarrow{\cong} \text{Rep}^{\text{adj}} U_q g \quad \text{Z/2Z fixed points, when } g = e_6.$$

for each exceptional  $g$

$\lambda \longleftrightarrow \text{bracket}$

$x \longleftrightarrow \text{R-matrix}$

## Conjecture<sup>(mst)</sup>

In  $Q_{\text{Except}}$ , the space of (closed) knotted trivalent graphs is one-dimensional,  
spanned by the empty diagram.

We need an algorithm to evaluate (and, ambitiously, a  
consistent one)!

## Examples

- adding an  $H$  in 3 different ways, and taking a linear combination,

$$[3] \begin{array}{c} \diagup \\ \diagdown \end{array} \in \text{span} \left\{ \begin{array}{c} \diagup \\ \diagdown \end{array}, \begin{array}{c} \diagdown \\ \diagup \end{array}, \begin{array}{c} \diagup \\ \diagup \end{array}, H, X \right\}$$

$$\bullet H - Y = \frac{[6]}{[2][3]} (X - Y) + [\lambda][\lambda-1] (-Y)$$

$$(\text{here } [k\lambda+\lambda] = w^k v^\ell - w^{-k} v^{-\ell})$$

(Using this we can find a relation between

$$Y, X, ) (, Y, X, )$$

and use this to evaluate knots up to 8 crossings.)

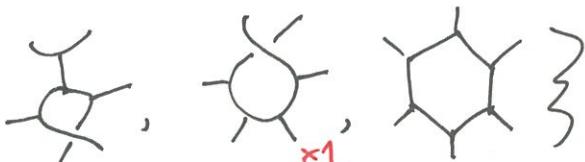

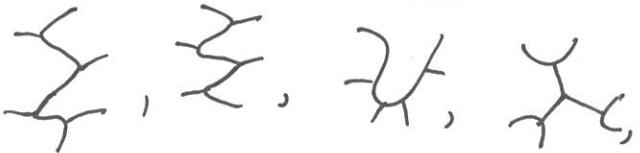

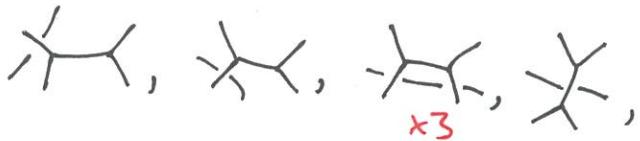

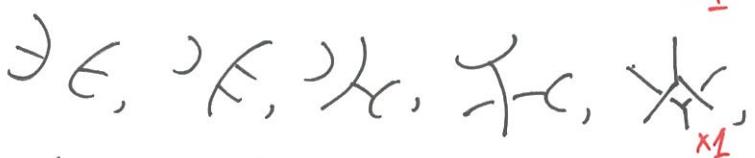

We have conjectural bases for

11

$$QE_{\text{Except}_4} = Q(v,w) \{ , \cup, \times, \times, \times \} \quad (\dim=5)$$

and  $\text{F}_3$  ( $\dim = 16$ )

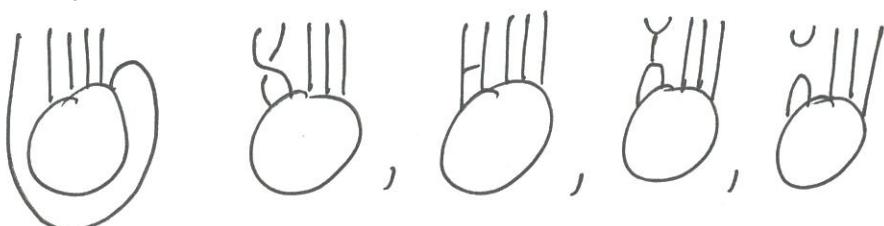

$$Q_{\text{Except}_6} = Q(v, w) \{ \rightarrow_C, \rightarrow_C^*, \neg, \neg\neg, \neg\neg\neg, \neg\neg\neg\neg \}$$

(d<sub>m</sub>=80)

but sometimes not all the rotations!

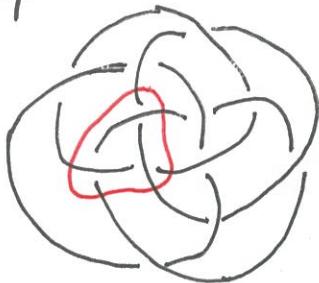

These have the nice property that they are closed under the operations

$\Rightarrow$  we get representations (over  $\mathbb{Q}(v, w)$ ) of the  $n \leq 6$  strand braid groups.

$\Rightarrow$  we can calculate the quantum exceptional polynomials for any link with "Conway width" at most 6.

$\Rightarrow$  in particular, all prime knots with  $\leq 14$  crossings and almost all <sup>prime</sup> links up to 12 crossings, except

repeatedly collapse digons  
(i.e. identify maximal rational tangles)  
then measure the width.

## Example

Unconditionally, this specialises to give  $U_q(g)$  knot invariants, which were previously too hard to compute.

It appears that  $L \in Q$  Except is of the form

$$d^k + \frac{[3][4][\lambda-6][\lambda+5]}{[1][2][\lambda-1]^{k+1}[\lambda]^{k+1}} E(L)$$

where  $E(L) \in \mathbb{Z}[v^{\pm 1}, w^{\pm 1}]$ .

Questions
